Model design

W4 Vector potentials

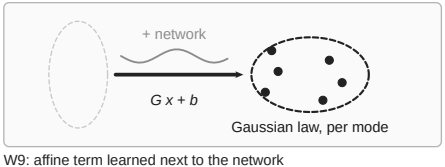

the output lies on the surface by construction

W4s B → −B equivariance

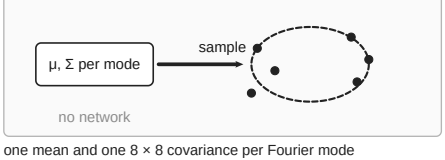

the velocity field is equivariant

W9, W10, W11 Affine term, Gaussian anchor

W9: affine term learned next to the network
W10: exact Gaussian field; W11: plus learned affine correction

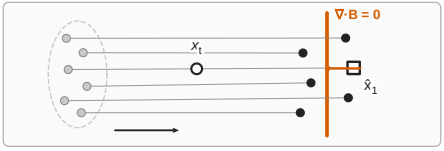

G0 Conditional Gaussian law

one mean and one 8 × 8 covariance per Fourier mode

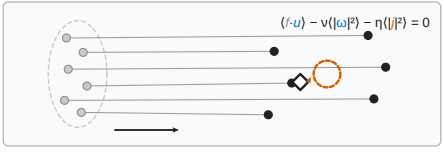

Training loss

W1 Divergence penalty

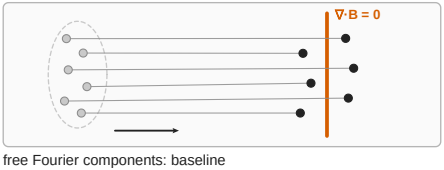

on the end-of-path prediction $\hat{x}_1 = x_t + (1 - t)\, v$

W5 Law-level stationarity loss

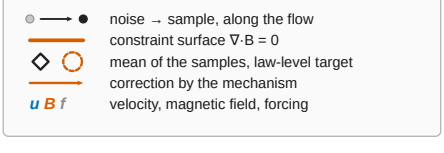

constrains a mean over samples, not each sample

W0 No constraint

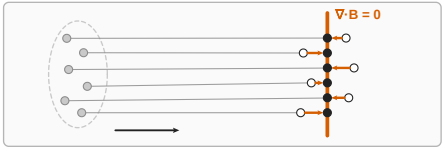

free Fourier components: baseline

Shared glyphs

Sampling procedure

W2 Final Leray projection

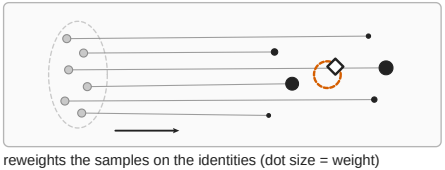

projection of the final samples onto the surface

W3 Projected flow

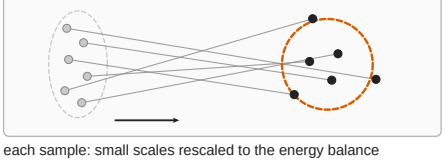

projected noise; projection of every integration stage

W7 Exponential tilting

reweights the samples on the identities (dot size = weight)

W8 Per-sample rescaling

each sample: small scales rescaled to the energy balance
