a **Optimal velocity field** $v(x, t)$

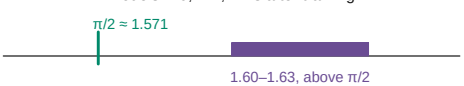

v = **Linear part** $A(t)\,x + b(t)$ + **The rest** non-linear

Gaussian data: exactly affine — Gaussian data: none

Conjecture (tested by a width scan, H21): a network narrower than the latent cannot carry the linear part

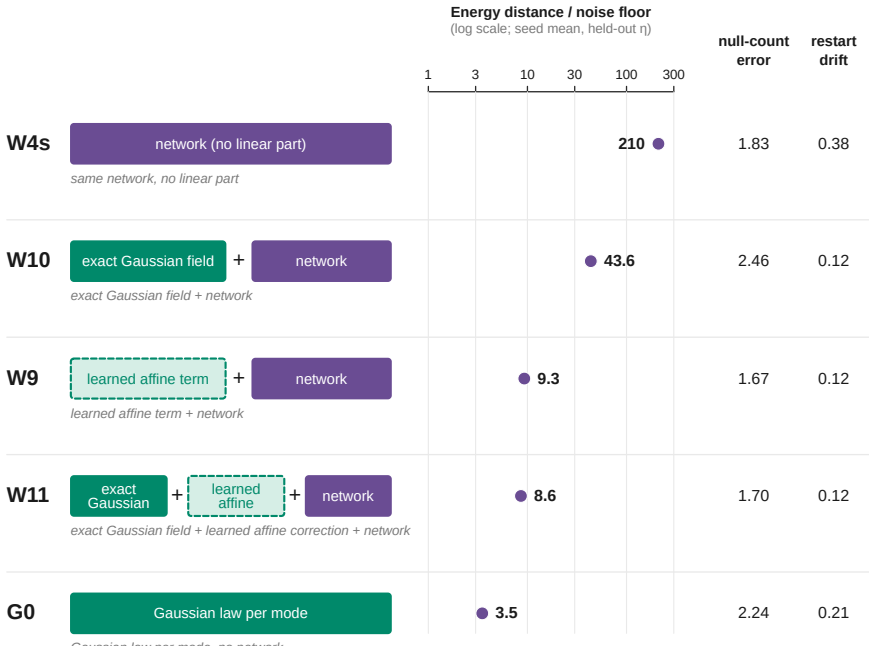

Measured: flow-matching loss of the plain models W0, W4, W4s after training

Samples over-dispersed: potentials models: 2 to 3 times too many null points

b **Four remedies** on the same glyphs

(relative values)

The Gaussian law alone is the closest in energy distance; the models with a learned affine term have fewer spurious null points and half its restart drift.
