a **Compared ensembles**

held-out η

Generated snapshots

Reference snapshots

from the solver

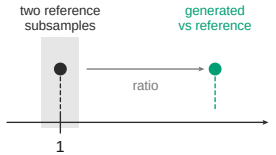

velocity *u*

field *B*

forcing *f*

b **Energy distance**

distance to reference / noise floor

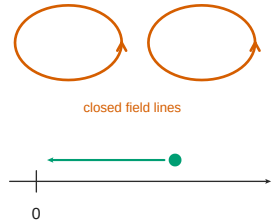

floor (grey band): mean of 10 splits of the reference trajectories into two halves

a perfect generator would score about 0.6, not 1

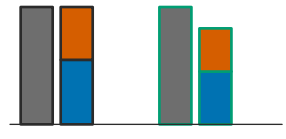

c **Divergence of B**

‖∇·B‖ / ‖∇B‖

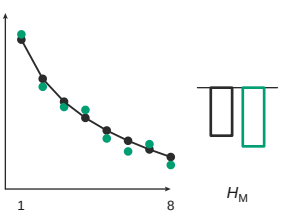

d **Energy balance**

injection vs ν + η dissipation

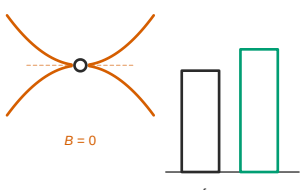

e **Spectrum, helicity**

$E_B(k)$ and mean H_M

f **Null points**

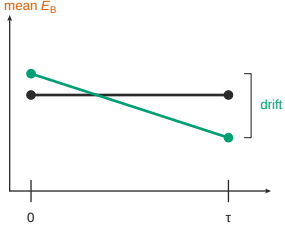

mean count of $B = 0$

g **Restart drift**

solver advances snapshots by τ = 4

mean E_B

h **Polarity symmetry**

$|P((u\cdot B) > 0) - ½|$
